The vertical red lines in Figure 1A and 1B indicate one SD to either side of the mean. From this, we can see that the population in Figure 1A has a SD of 20, whereas the population in Figure 1B has a SD of 50. A useful rule of thumb is that roughly 67% of the values within a normally distributed population will reside within one SD to either side of the mean.

Statistical use and meaning. Relative risk is used in the statistical analysis of the data of ecological, cohort, medical and intervention studies, to estimate the strength of the association between exposures (treatments or risk factors) and outcomes. Mathematically, it is the expressed as the incidence rate of the outcome in the exposed group, , divided by the outcome of the unexposed group, .

In survival analysis, the hazard ratio (HR) is the ratio of the hazard rates corresponding to the conditions described by two levels of an explanatory variable. For example, in a drug study, the treated population may die at twice the rate per unit time of the control population. The hazard ratio would be 2, indicating higher hazard of death from the treatment.
