A memristor is a two-terminal electronic device whose conductance can be precisely modulated by charge or flux through it. Here we experimentally demonstrate a nanoscale silicon-based memristor device and show that a hybrid system composed of complementary metal-oxide semiconductor neurons and memristor synapses can support important synaptic functions such as spike timing dependent plasticity.

In 2010, Lu et. al utilized Ag/Si memristors incorporated into crossbar synapse networks with CMOS based pre and post synaptic neurons to effectively demonstrate that changes in both pulse height and width from CMOS neurons caused corresponding changes in memductance of memristor synapse. This proved the memristor neuromorphic circuit exhibited behavior analogous to spike timing dependant plasticity, a process which governs strength of interconnects between neurons and vital to learning and ...

In this paper we first describe how nanoscale synaptic devices can be integrated into neuro-computing architectures to build large-scale neural networks, and then propose a new hybrid memristor-CMOS neuromorphic circuit that emulates the behavior of real synapses, including their temporal dynamics aspects, for exploring and understanding the principles of neural computation and eventually building brain-inspired computing systems.

Moreover, the device was used as a threshold neuron along with drift memristor synapse based on TaO<sub>x</sub> to emulate STDP learning rule. Because the conductance of the device gradually increases according to applied voltage and then abruptly decreases under no applied voltage, the device can be used as a threshold neuron.
