Data for statistical studies are obtained by conducting either experiments or surveys. Experimental design is the branch of statistics that deals with the design and analysis of experiments. The methods of experimental design are widely used in the fields of agriculture, medicine, biology, marketing research, and industrial production.

A quasi experimental design is one in which treatment allocation is not random. An example of this is given in table 9.1 in which injuries are compared in two dropping zones. This is subject to potential biases in that the reason why a person is allocated to a particular dropping zone may be related to their risk of a sprained ankle.

Experimental Design. By Saul McLeod, updated 2017. Experimental design refers to how participants are allocated to the different groups in an experiment. Types of design include repeated measures, independent groups, and matched pairs designs. Probably the commonest way to design an experiment in psychology is to divide the participants into two groups, the experimental group, and the control group, and then introduce a change to the experimental group and not the control group.

Design processes bring together all such aspects including specific statistical analysis techniques. Most designs given in this chapter involve testing by analysis of variance (ANOVA). The chapter covers basic material by detailing the nature and terminology of experimental design for simple experiments.

The design of experiments is the design of any task that aims to describe and explain the variation of information under conditions that are hypothesized to reflect the variation. The term is generally associated with experiments in which the design introduces conditions that directly affect the variation, but may also refer to the design of quasi-experiments, in which natural conditions that influence the variation are selected for observation. In its simplest form, an experiment aims at predic

Design of experiments - Wikipedia

This is an experimental design because we are statistically determining whether a change in one variable, called a treatment, causes an effect in the other variable, sometimes called the effect. Unlike correlational variables, which occur simultaneously, in causal experimental designs, one variable occurs before the other and (drum roll) causes the other to change.
